Motivation

Networks (Power, Social, etc.)

- Large scale infrastructures
- Multi-agent Multiple interacting entities/users
- Heterogeneous Different physical or technological constraints per agent; different objectives per agent
- Challenge: Optimizing the performance of a network ...
 - Computation : Problem size too big!
 - ► Communication : Not all communication links at place; link failures
 - Information privacy: Agents may not want to share information with everyone (e.g. facebook)

Hilary Term 2021-22 C20 Distributed Systems

Why go decentralized/distributed?

- Scalable methodology
 - Communication :

Decentralized: With some central authority

Distributed: Only between neighbours

- Computation : Only local; in parallel for all agents
- 2 Information privacy
 - Agents do not reveal information about their preferences (encoded by objective and constraint functions) to each other
- Resilience to communication failures
- Numerous applications
 - Wireless networks
 - Optimal power flow

Multi-agent problem classes

- Electric vehicle charging control
- Energy management in building networks

Hilary Term 2021-22

January 28, 2022

Motivating example: Electric vehicle charging

- Charging rate of each vehicle : x_i (in units of power)
- Electric vehicles are like batteries : X_i encodes limits on charging rate

Price depends on everybody's consumption

minimize
$$\sum_{i} \mathbf{x}_{i}^{\mathsf{T}} p(\sum_{i} \mathbf{x}_{i})$$
 [price function $p(\cdot)$]

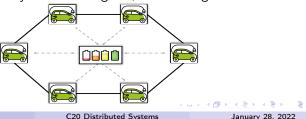

subject to : $x_i \in X_i$, for all i [limitations on the charging rate]

Decentralized : All agents with a central authority/coordinator

Decentralized vs. Centralized: Agents "broadcast" only tentative information not everything

2 Distributed : Only with some agents, termed neighbours

Multi-agent problem classes

Decentralized vs. Distributed

Cost coupled problems

minimize
$$F(x_1, ..., x_m)$$

subject to $x_i \in X_i, \ \forall i = 1, ..., m$

- Agents have separate decisions : x_i for agent i
- Agents have separate constraint sets : X_i for agent i
- Agents aim at minimizing a single objective function F that couples their decisions

Multi-agent problem classes

Decision coupled problems

minimize
$$\sum_{i=1}^{m} f_i(x)$$

subject to $x \in X_i, \ \forall i = 1, ..., m$

- Agents have a common decision : x for all agents
- Agents have separate constraint sets: X_i for agent i
- Agents have separate objective functions : f_i for agent i

| Hilary Term 2021-22 | C20 Distributed Systems | January 28, 2022 | 9 / 26

Multi-agent problem classes

Hilary Term 2021-22

Constraint coupled problems (cont'd)

minimize
$$\sum_{i=1}^{m} f_i(x_i)$$

subject to $x_i \in X_i, \ \forall i = 1, \dots, m$
 $\sum_{i=1}^{m} g_i(x_i) \leq 0$

- Agents have separate decisions : x_i for agent i
- Agents have separate constraint sets : X_i for agent i
- Agents have a common constraint that couples their decisions, i.e. $\sum_i g_i(x_i) \le 0$

C20 Distributed Systems

Multi-agent problem classes

Constraint coupled problems: Electric vehicle charging

- Charging rate of each vehicle : x_i (in units of power)
- Electric vehicles are like batteries : X_i encodes limits on charging rate

Price independent of others consumption

minimize
$$\sum_{i} c_{i}^{\mathsf{T}} x_{i}$$
 [charging cost]

subject to : $x_i \in X_i$, for all i [limitations on the charging rate]

$$\sum_{i} \left(A_{i} \times_{i} - \frac{b}{m} \right) \leq 0 \qquad [power grid constraint]$$

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022

10 / 26

Can we transform one problem class to another?

From decision coupled to constraint coupled problems

minimize
$$\sum_{i} f_{i}(x_{i})$$

subject to $x_{i} \in X_{i}, \ \forall i = 1, ..., m$
 $x_{i} = x, \ \forall i = 1, ..., m$

- Introduce m new decision vectors, as many as the agents : x_i , i = 1, ..., m
- Introduce consistency constraints : make sure all those auxiliary decisions are the same, i.e. $x_i = x$ for all i = 1, ..., m
- Price to pay: Number of constraints grows with the number of agents

Hilary Term 2021-22 C20 Distributed Systems January 28, 2022 12/2

Can we transform one problem class to another?

From cost coupled to constraint coupled problems

minimize
$$\gamma = \sum_{i} \frac{\gamma}{m}$$

subject to $x_i \in X_i, \ \forall i = 1, ..., m$
 $F(x_1, ..., x_m) \leq \gamma$

- Introduce an additional scalar epigraphic variable γ
- Move coupling to the constraints, i.e. $F(x_i, ..., x_m) \le \gamma$
- Price to pay: Coupling can not be split among several functions, each of them depending only on x_i , i.e. not in the form $\sum_i g_i(x_i) \leq 0$

4□ > 4回 > 4 亘 > 4 亘 > □ ● 900 Hilary Term 2021-22 C20 Distributed Systems January 28, 2022

Can we transform one problem class to another?

Yes, but ...

- We can transform from some problem classes to others
- Often those reformulations are useful
- However, they come with drawbacks :
 - may increase number of decision variables.
 - or lead to non-separable constraints,
 - or non-differentiable objective functions

So necessary to develop algorithms tailored to each problem class

Can we transform one problem class to another?

From decision coupled to cost coupled problems

minimize
$$F(x_1, \dots, x_m) = \sum_i f_i(x) + I_{X_i}(x)$$

subject to : no constraints

• Lift the constraints in the objective function via characteristic functions, i.e., for each i.

$$I_{X_i}(x) = \begin{cases} 0 & \text{if } x \in X_i; \\ +\infty & \text{otherwise.} \end{cases}$$

- New problem does not have any constraints
- Price to pay: The new objective function is not differentiable, even if each f_i is differentiable

4 D > 4 B > 4 E > 4 E > E 990 Hilary Term 2021-22 C20 Distributed Systems January 28, 2022 14 / 26

Part I.A: Decentralized algorithms

Cost coupled problems

Cost coupled problems 1

minimize
$$F(x_1, ..., x_m)$$

subject to $x_i \in X_i$. $\forall i = 1, ..., m$

- Denote by x^* a minimizer of the cost coupled problem
- Denote by F^* its minimum value

Hilary Term 2021-22 C20 Distributed Systems

イロナ (部) (注) (注)

^{1.} Throughout we assume that all functions and sets are convex. Hilary Term 2021-22 C20 Distributed Systems

Mathematical prelims: Lipschitz & Contraction mappings

• Let $T: X \to X$. We call T a Lipschitz mapping if there exists $\alpha > 0$ such that

$$||T(x) - T(y)|| \le \alpha ||x - y||$$
, for all $x, y \in X$

- We call a Lipschitz mapping T contraction mapping if $\alpha \in [0,1)$
- Parameter $\alpha \in [0,1)$ is called the modulus of contraction of T
- We should always specify the norm

Convergence of contractive iterations

Assume T is a contraction with modulus $\alpha \in [0,1)$ and X is a closed set.

- T has a unique fixed-point $T(x^*) = x^*$
- 2 The Picard-Banach iteration x(k+1) = T(x(k)) converges to x^* geometrically, i.e.

$$||x(k) - x^*|| \le \alpha^k ||x(0) - x^*||$$
, for all $k \ge 0$

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022

The Jacobi algorithm

Iterative algorithm

Initialize: Select (arbitrarily) $x_i(0) \in X_i$, for all i = 1, ..., m

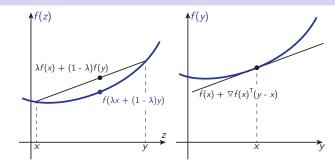

For each iteration k = 1, ...

- Collect $x(k) = (x_1(k), \dots, x_m(k))$ from central authority
- 2 Agents update their local decision in parallel, i.e. for all $i=1,\ldots,m$

$$x_i(k+1) = \arg\min_{x_i \in X_i} F(x_1(k), \dots, x_{i-1}(k), x_i, x_{i+1}(k), \dots, x_m(k))$$

end for

Mathematical prelims: Convexity vs strong convexity

• Strong convexity is "stronger" than convexity – uniqueness of optimum & lower bound on growth

$$f(y) \ge f(x) + \nabla f(x)^{T} (y - x) + \sigma ||y - x||^{2}$$
, where $\sigma > 0$

- We can fit a quadratic function between the "true" function and its linear approximation
- For quadratic functions strong is the same with strict convexity

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022 18 / 26

The Jacobi algorithm

Agents coupled via a single objective function

minimize
$$F(x_1,...,x_m)$$

subject to : $x_i \in X_i$, $\forall i = 1,...,m$

- Collect $x(k) = (x_1(k), \dots, x_m(k))$ from central authority
- 2 Agents update their local decision in parallel

$$x_i(k+1) = \arg\min_{x_i \in X_i} F(x_1(k), \dots, x_{i-1}(k), x_i, x_{i+1}(k), \dots, x_m(k))$$

- Block coordinate descent method; agents act in best response
- Parallelizable method : Agent i uses the k-th updates of all agents

Jacobi algorithm : Convergence

Theorem: Convergence of Jacobi algorithm

If ${\it F}$ is differentiable and there exists small enough γ such that

$$T(x) = x - \gamma \nabla F(x)$$

is a contraction mapping (modulus in [0,1)), then there exists a minimizer x^* of the cost coupled problem such that

$$\lim_{k\to\infty}\|x(k)-x^*\|=0$$

- Best response but a gradient step appears in convergence
- A sufficient condition for T to be a contractive map is F to be a strongly convex function
- Can we relax this condition?

| Hilary Term 2021-22 | C20 Distributed Systems | January 28, 2022 | 21/26

Regularized Jacobi algorithm: Convergence

Theorem: Convergence of regularized Jacobi algorithm

Assume that F is convex and ∇F is Lipschitz continuous with constant L. Assume also that

$$c > \frac{m-1}{2m-1} \sqrt{m}L$$

We then have that $\lim_{k\to\infty} ||F(x(k)) - F^*|| = 0$

- Algorithm convergences in value, not necessarily in iterates, i.e. not necessarily $\lim_{k\to\infty} \|x(k) x^*\| = 0$
- Penalty term c increases as $m \to \infty$
- The more agents the "slower" the overall process

The regularized Jacobi algorithm

- Collect $x(k) = (x_1(k), \dots, x_m(k))$ from central authority
- 2 Agents update their local decision in parallel

$$x_{i}(k+1) = \arg\min_{\mathbf{x}_{i} \in X_{i}} F\left(x_{1}(k), \dots, x_{i-1}(k), x_{i}, x_{i+1}(k), \dots, x_{m}(k)\right) + \frac{\mathbf{c}\|\mathbf{x}_{i} - \mathbf{x}_{i}(k)\|_{2}^{2}$$

- Jacobi algorithm + regularization term
- Penalty term acts like "inertia" from previous tentative solution of agent i
- New objective function is strongly convex due to regularization

| Hilary Term 2021-22 | C20 Distributed Systems | January 28, 2022 | 22/26

The Gauss-Seidel algorithm

- Collect $x(k) = (x_1(k+1), \dots, x_{i-1}(k+1), x_i(k), \dots, x_m(k))$
- Agent i updates

$$x_{i}(k+1)$$
= $\arg\min_{x_{i} \in X_{i}} F(x_{1}(k+1), \dots, x_{i-1}(k+1), x_{i}, x_{i+1}(k), \dots, x_{m}(k))$

- Block coordinate descent method; agents act in best response
- Sequential : Agent i uses the (k + 1)-th updates of preceding agents
- Similar convergence results with Jacobi algorithm : If F is strongly convex (strict convexity is sufficient) with respect to each individual argument, then $\lim_{k\to\infty}\|F(x(k))-F^*\|=0$

→ロト→団ト→ミト→ミトーミーのQで

Summary

Decentralized algorithms for cost coupled problems

minimize
$$F(x_1, ..., x_m)$$

subject to $x_i \in X_i$, $\forall i = 1, ..., m$

- The Jacobi algorithm : parallel updates
 F differentiable and strongly convex
- The regularized Jacobi algorithm : parallel updates F differentiable and just convex
- The Gauss-Seidel algorithm : sequential updates F differentiable and strongly convex per agent's decision
 - \Rightarrow For quadratic functions $x^{T}Qx$:
 - convex if $Q \ge 0$; strongly convex if Q > 0
 - Strong convexity = strict convexity

Summary

Decentralized algorithms for cost coupled problems

minimize
$$F(x_1, ..., x_m)$$

subject to $x_i \in X_i$, $\forall i = 1, ..., m$

- The Jacobi algorithm : parallel updates
 F differentiable and strongly convex
- The regularized Jacobi algorithm : parallel updates
 F differentiable and just convex
- The Gauss-Seidel algorithm : sequential updates F differentiable and strongly convex per agent's decision
 - \Rightarrow For quadratic functions $x^T Qx$:
 - convex if $Q \ge 0$; strongly convex if Q > 0
 - Strong convexity = strict convexity

The proximal minimization algorithm

• Consider a differentiable function F. The following problems are equivalent

Standard minimization program

minimize F(x)subject to : $x \in X$

Proximal minimization program

minimize
$$F(x) + \frac{1}{2c} ||x - y||^2$$

subject to : $x \in X$, $y \in \mathbb{R}^n$

- The proximal problem has an objective function which is differentiable and strongly convex (for any fixed y)
- We can solve it iteratively via the Gauss-Seidel algorithm; converges for any c > 0 (see Lecture 1)
- Alternate between minimizing x and y

Part I.B: Decentralized algorithms

Decision coupled problems

- Decentralized solution roadmap
 - 1 The main algorithm for this is the Alternating Direction Method of Multipliers (ADMM)
 - 2 The predecessor of ADMM is the Augmented Lagrangian algorithm
 - 3 The Augmented Lagrangian is in turn based on the Proximal algorithm

Proximal ⇒ Augmented Lagrangian ⇒ ADMM

The proximal minimization algorithm

• The following problems are equivalent

Standard minimization program

Hilary Term 2021-22

minimize F(x)subject to : $x \in X$ Proximal minimization program

minimize
$$F(x) + \frac{1}{2c} ||x - y||^2$$

subject to : $x \in X$, $y \in \mathbb{R}^n$

Proximal algorithm:

$$(k+1) = \arg\min_{x \in X} F(x) + \frac{1}{2c} ||x - y(k)||^2$$

$$y(k+1) = x(k+1)$$

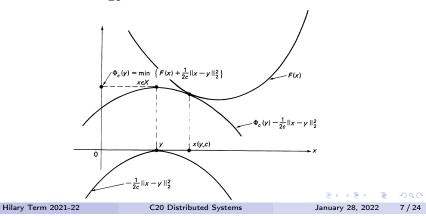

$$x(k+1) = \arg\min_{x \in X} F(x) + \frac{1}{2c} ||x - x(k)||^2$$

The proximal minimization algorithm

Geometric interpretation

- Let $\Phi_c(y) = \min F(x) + \frac{1}{2c} ||x y||^2$ achieved at x = x(y, c)
- Hence, $\Phi_c(y) = F(x_{(y,c)}) + \frac{1}{2c} \|x_{(y,c)} y\|^2 \le F(x) + \frac{1}{2c} \|x y\|^2$

 $\Rightarrow \Phi_c(y) - \frac{1}{2c} ||x - y||^2 \le F(x)$, with equality at x = x(y, c)

The proximal minimization algorithm

Geometric interpretation

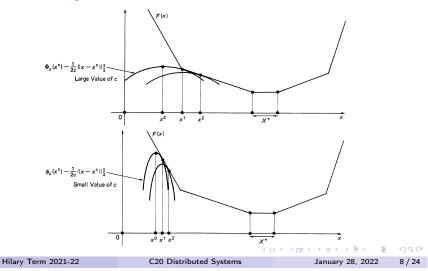

• Effect of the growth of F (flat and steep functions)

The proximal minimization algorithm

Geometric interpretation

• Effect of large and small values of c

The augmented Lagrangian algorithm

• Consider the following problems

Standard program

$$\operatorname{minimize}_{x \in X} F(x)$$

subject to : Ax = b

Augmented program

minimize_{$$x \in X$$} $F(x) + \frac{c}{2} ||Ax - b||^2$
subject to : $Ax = b$

- Trivially equivalent problems : For any feasible *x*, the "proxy" term becomes zero
- Resembles the structure of the proximal algorithm
- Ax = b models complicating constraints: if $F(x) = \sum_i f_i(x_i)$ and $X = X_1 \times ... \times X_m$, then Ax = b models coupling among agents' decisions

Hilary Term 2021-22 C20 Distributed Systems January 28, 2022 10 / 24

The augmented Lagrangian algorithm

• Construct the Lagrangian of the augmented program

$$L_c(x,\lambda) = F(x) + \lambda^{T}(Ax - b) + \frac{c}{2}||Ax - b||^{2}$$

Augmented Lagrangian algorithm:

- **1** $x(k+1) = \arg\min_{x \in X} F(x) + \lambda(k)^{\top} (Ax b) + \frac{c}{2} ||Ax b||^2$
- For simplicity we assumed a unique minimum for the primal variables; this depends on A
- Apply a primal-dual scheme : minimization for primal followed by gradient ascent for dual

Hilary Term 2021-22

Hilary Term 2021-22

C20 Distributed Systems

4 D > 4 D > 4 E > 4 E > E 900 January 28, 2022

Proof

Augmented Lagrangian algorithm:

- $(k+1) = \arg\min_{x \in X} F(x) + \lambda (k)^{\top} (Ax b) + \frac{c}{2} ||Ax b||^{2}$
- Notice that the dual function of the original problem is given by

$$q(y) = \min_{x \in X} F(x) + y^{\mathsf{T}} (Ax - b)$$

where y contains the dual variables associated with $Ax \le b$

Step 1: Equivalently write the primal minimization step as

$$\min_{x \in X} F(x) + \lambda(k)^{\mathsf{T}} (Ax - b) + \frac{c}{2} ||Ax - b||^{2}$$

$$= \min_{x \in X, \ z, \ Ax - b = z} F(x) + \lambda(k)^{\mathsf{T}} z + \frac{c}{2} ||z||^{2}$$

The minimizers are denoted by x(k+1) and z(k+1)

The augmented Lagrangian algorithm

Augmented Lagrangian algorithm:

- **1** $x(k+1) = \arg\min_{x \in X} F(x) + \lambda(k)^{\mathsf{T}} (Ax b) + \frac{c}{2} ||Ax b||^2$

Theorem: Convergence of Augmented Lagrangian algorithm

For any c > 0, we have that :

• there exists an optimal dual solution λ^* such that

$$\lim_{k \to \infty} \|\lambda(k) - \lambda^*\| = 0$$

2 primal iterates converge to the optimal value F^* , i.e.

$$\lim_{k\to\infty} \|F(x(k)) - F^*\| = 0$$

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022

Proof (cont'd)

Step 2:

 Dualize the coupling constraint in Step 1 using multipliers y and consider the optimum of the dual problem

$$y^* = \arg\max_{y} \left\{ \min_{\mathbf{x} \in X} \left(F(\mathbf{x}) + y^{\mathsf{T}} (A\mathbf{x} - b) \right) + \min_{\mathbf{z}} \left((\lambda(k) - y)^{\mathsf{T}} \mathbf{z} + \frac{c}{2} \|\mathbf{z}\|^2 \right) \right\}$$

• Using the definition of the q(y) this is equivalent to

$$y^* = \arg \max_{\mathbf{z}} \left\{ q(y) + \min_{\mathbf{z}} \left((\lambda(k) - y)^{\mathsf{T}} \mathbf{z} + \frac{c}{2} \|\mathbf{z}\|^2 \right) \right\}$$

• The inner minimization is an unconstrained quadratic program; calculate its minimizer by setting the objective's gradient equal to zero

$$\overline{z} = \frac{y - \lambda(k)}{c}$$
 and hence $z(k+1) = \frac{y^* - \lambda(k)}{c}$

Proof (cont'd)

Step 3:

• Substituting back the value of \overline{z}

$$y^* = \arg\max_{y} \left\{ q(y) + \min_{\mathbf{z}} \left((\lambda(k) - y)^{\mathsf{T}} \mathbf{z} + \frac{c}{2} \| \mathbf{z} \|^2 \right) \right\}$$
$$= \arg\max_{y} \left\{ q(y) - \frac{1}{2c} \| y - \lambda(k) \|^2 \right\}$$

• At the same time, due to the equality constraint in Step 1.

$$z(k+1) = Ax(k+1) - b, \text{ hence}$$

$$\lambda(k+1) = \lambda(k) + c(Ax(k+1) - b) \implies \lambda(k+1) = y^*$$

which in turn implies that

$$\lambda(k+1) = \arg\max_{\mathbf{y}} q(\mathbf{y}) - \frac{1}{2c} \|\mathbf{y} - \lambda(k)\|^2$$

Hilary Term 2021-22

C20 Distributed Systems

Back to decision coupled problems

Recall the equivalence between decision and constraint coupled problems

Decision coupled problem

minimize
$$\sum_{i} f_{i}(x)$$

subject to : $x \in X_i$, $\forall i$

Constraint coupled problem

minimize
$$\sum_{i} f_i(x_i)$$

subject to : $x_i \in X_i$, $\forall i$

 $x_i = z, \forall i$

• We will show that this constraint coupled problem is in the form of

$$\min_{x \in X} F(x) \\
\text{subject to : } Ax = b$$

Proof (cont'd)

Step 4: Putting everything together ...

• The augmented Lagrangian primal dual scheme

$$(k+1) = \arg\min_{x \in X} F(x) + \lambda(k)^{\top} (Ax - b) + \frac{c}{2} ||Ax - b||^{2}$$

... is equivalent to

- Proximal algorithm for the dual function q(y)!
- It converges for any c as q(y) is the dual function thus always concave, i.e. $\lim_{k\to\infty} \|\lambda(k) - \lambda^*\| = 0$ for some optimal λ^*
- For the primal variables we can only show something slightly weaker : they asymptotically achieve the optimal value F^*

Hilary Term 2021-22

C20 Distributed Systems

Decision coupled problems

Consider the following asignements:

Decision vector

$$x \leftarrow (x_1, \ldots, x_m, z)$$

Constraint sets

$$X \leftarrow X_1 \times \ldots \times X_m \times \mathbb{R}^n$$

Objective function

$$F(x_1,\ldots,x_m,\mathbf{z}) \leftarrow \sum_i f_i(x_i)$$

Matrices A and b :

Hilary Term 2021-22

$$Ax = b \iff \begin{bmatrix} -1 & 0 & \dots & 0 & 1 \\ 0 & -1 & \dots & 0 & 1 \\ \vdots & & \vdots & & \vdots \\ 0 & 0 & \dots & -1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_m \\ z \end{bmatrix} = 0$$

• Dual variable : $\lambda \leftarrow (\lambda_1, \dots, \lambda_m)$

$$\lambda(k)^{\mathsf{T}}(Ax - b) = \sum_{i} \lambda_{i}^{\mathsf{T}}(k)(\mathbf{z} - x_{i}) \text{ and } ||Ax - b||^{2} = \sum_{i} ||\mathbf{z} - x_{i}||^{2}$$

Decision coupled problems

Augmented Lagrangian for the reformulated constraint coupled problem

Primal update

$$(x_1(k+1),...,x_m(k+1),z(k+1))$$

$$= \arg \min_{x_1 \in X_1,...,x_m \in X_m,z} \sum_i f_i(x_i) + \lambda_i^{\top}(k)(z-x_i) + \frac{c}{2} ||z-x_i||^2$$

Oual update

$$\lambda_i(k+1) = \lambda_i(k) + c(z(k+1) - x_i(k+1))$$

- Primal update in the form cost coupled problems via a single function $\sum_{i} f_{i}(x_{i}) + \lambda_{i}(k)^{T}(z - x_{i}) + \frac{c}{2} ||z - x_{i}||^{2}$
- Can solve via Gauss-Seidel algorithm, alternating between minimizing with respect to (x_1, \ldots, x_m) and z4□ > 4回 > 4 亘 > 4 亘 > □ ● 900

Primal update for z information from central authority

$$z = \frac{1}{m} \sum_{i} x_{i} - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i = \arg\min_{x_i \in X_i} f_i(x_i) - \lambda_i(k)^{\mathsf{T}} x_i + \frac{c}{2} \|\mathbf{z} - x_i\|^2$$

end loop

Oual update in parallel for all agents

$$\lambda_i(k+1) = \lambda_i(k) + c(z(k+1) - x_i(k+1))$$

• Nested iteration with Gauss-Seidel inner loop – Can we do any better?

Decision coupled problems

Primal update: Can solve via Gauss-Seidel algorithm, alternating between minimizing with respect to (x_1, \ldots, x_m) and z

$$(x_1(k+1),...,x_m(k+1),x(k+1))$$

$$= \arg \min_{x_1 \in X_1,...,x_m \in X_m,z} \sum_i f_i(x_i) + \lambda_i^{\top}(k)(z-x_i) + \frac{c}{2} ||z-x_i||^2$$

• Update of z: Unconstrained quadratic minimization with respect to z. Take the derivative and set it equal to zero leads to

$$\mathbf{z} = \frac{1}{m} \sum_{i} \mathbf{x}_{i} - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

• Update of x_1, \ldots, x_m : For fixed **z** problem is separable across agents (no longer coupled in the cost). Hence for all i,

$$x_i = \arg\min_{x_i \in X_i} f_i(x_i) - \lambda_i(k)^{\mathsf{T}} x_i + \frac{c}{2} \|\mathbf{z} - x_i\|^2$$

Hilary Term 2021-22

C20 Distributed Systems

Decision coupled problems

What if we only do one Gauss-Seidel pass?

Primal update for z information from central authority

$$z(k+1) = \frac{1}{m} \sum_{i} x_{i}(k) - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i(k+1) = \arg\min_{x_i \in X_i} f_i(x_i) - \lambda_i(k)^{\mathsf{T}} x_i + \frac{c}{2} \|\mathbf{z}(k+1) - x_i\|^2$$

Oual update in parallel for all agents

$$\lambda_i(k+1) = \lambda_i(k) + c(z(k+1) - x_i(k+1))$$

• Does this scheme converge? ADMM provides the answer! Lecture 3

Recap

Decision coupled problems

minimize
$$\sum_{i} f_{i}(x)$$

subject to

$$x \in X_i, \forall i = 1, \ldots, m$$

Intriduced three different algorithms

- Proximal minimization algorithm
- Augmented Lagrangian algorithm
- Augmented Lagrangian with one pass of the inner loop = ADMM

Proximal ⇒ Augmented Lagrangian ⇒ ADMM

C20 Distributed Systems Hilary Term 2021-22 January 28, 2022

Recap: Augmented Lagrangian algorithm

Inner lopp: Gauss-Seidel algorithm!

begin loop

Primal update for z information from central authority

$$\mathbf{z} = \frac{1}{m} \sum_{i} x_{i} - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i = \arg\min_{\mathbf{x}_i \in X_i} f_i(\mathbf{x}_i) - \lambda_i(\mathbf{k})^{\mathsf{T}} \mathbf{x}_i + \frac{c}{2} \|\mathbf{z} - \mathbf{x}_i\|^2$$

end loop

Oual update in parallel for all agents

$$\lambda_i(k+1) = \lambda_i(k) + c(\mathbf{z}(k+1) - \mathbf{x}_i(k+1))$$

Hilary Term 2021-22

C20 Distributed Systems

Hilary Term 2021-22

Example (cont'd)

- Decision coupled problem with 2 agents; notice that $f_1(x) = f_2(x) = 0$
- Consider k = 0 and focus at the **inner loop** of the Augmented Lagrangian algorithm
- Recall that $\lambda_1(0) = \lambda_2(0) = 0$

Outer loop at k = 0; main steps of inner loop

- 2 $x_1 \leftarrow \arg\min_{x_1 \in X_1} -\lambda_1(0)x_1 + \frac{c}{2} \|\mathbf{z} x_1\|^2 = \arg\min_{x_1 \in X_1} \frac{c}{2} \|\mathbf{z} x_1\|^2$ $x_2 \leftarrow \arg\min_{x_2 \in X_2} -\lambda_2(0)x_2 + \frac{c}{2} \|\mathbf{z} x_2\|^2 = \arg\min_{x_2 \in X_2} \frac{c}{2} \|\mathbf{z} x_2\|^2$
- Second step exhibits a nice structure and geometric interpretation
- Solve the unconstrained quadratic program and project on the constraint set $(X_1 \text{ and } X_2, \text{ respectively})$

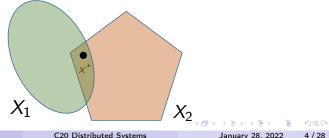

Example

Feasibility problem – part of Question 4, Example Paper

Find a point x^* at the intersection (assumed to be non-empty) of two (possibly different) convex sets X_1 and X_2 , i.e.

minimize 0 [any constant would work] subject to
$$x \in X_1$$
 and $x \in X_2$

Apply Augmented Lagrangian algorithm initializing at $\lambda_1(0) = \lambda_2(0) = 0$.

Example (cont'd)

- Denote by $\Pi_{X_i}[z]$ the projection of z on the set X_i
- Inner loop becomes then ...

Outer loop at k = 0; main steps of inner loop

1
$$z = \frac{x_1 + x_2}{2}$$

• This is just the Gauss-Seidel to solve the problem

$$\text{minimize}_{\mathbf{z}, x_1 \in X_1, x_2 \in X_2} \frac{c}{2} \sum_{i=1,2} \|\mathbf{z} - x_i\|^2$$

• Hence it converges to the minimum, which occurs when $x_1 = x_2 = z$

Example (cont'd)

• Since upon convergence of the inner loop $x_1 = x_2 = z$, then the outer loop update becomes

$$\lambda_i(1) = \lambda_i(0) + c(z(1) - x_i(1)) = 0$$
, for $i = 1, 2$

- Similarly, $\lambda_i(k) = 0$ for all k > 0
- Effectively we only have one loop!

Simplified single-loop algorithm

- Averaging step : $z(k+1) = \frac{x_1(k) + x_2(k)}{2}$
- Parallel projections : $x_1(k+1) = \prod_{X_1} \left[z(k+1) \right]$ and $x_2(k+1) = \prod_{X_2} \left[z(k+1) \right]$

Hilary Term 2021-22

C20 Distributed Systems

For decision coupled problems ...

Augmented Lagrangian with one Gauss-Seidel pass = ADMM

Primal update for z information from central authority

$$z(k+1) = \frac{1}{m} \sum_{i} x_{i}(k) - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i(k+1) = \arg\min_{x_i \in X_i} f_i(x_i) - \lambda_i(k)^{\mathsf{T}} x_i + \frac{c}{2} ||z(k+1) - x_i||^2$$

Oual update

$$\lambda_i(k+1) = \lambda_i(k) + c(z(k+1) - x_i(k+1))$$

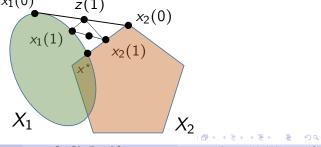

Example (cont'd)

Simplified single-loop algorithm

- Parallel projections :

$$x_1(k+1) = \prod_{X_1} [z(k+1)]$$
 and $x_2(k+1) = \prod_{X_2} [z(k+1)]$

Schematic illustration of the single-loop iterations

For decision coupled problems ...

Equivalent notation in line with ADMM literature (the roles of x and z are reversed) - only notational change!

Primal update for x information from central authority

$$x(k+1) = \frac{1}{m} \sum_{i} z_{i}(k) - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for z_i in parallel for all agents

$$z_i(k+1) = \arg\min_{z_i \in X_i} f_i(z_i) - \lambda_i(k)^{\mathsf{T}} z_i + \frac{c}{2} ||x(k+1) - z_i||^2$$

Oual update

$$\lambda_i(k+1) = \lambda_i(k) + c(x(k+1) - z_i(k+1))$$

The Alternating Direction Method of Multipliers (ADMM)

- ADMM even more general than decision coupled problems
- Splitting algorithm : decouples optimization across groups of variables

Group variables

minimize
$$F_1(x) + F_2(Ax)$$

subject to : $x \in C_1$, $Ax \in C_2$

Equivalent reformulation

minimize
$$F_1(x) + F_2(z)$$

subject to : $x \in C_1$, $z \in C_2$
 $Ax = z$

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022

11 / 28

Decision coupled problems as a special case again

Original problem

minimize
$$\sum_{i} f_{i}(x)$$

subject to : $x \in X_{i}, \forall i$

ADMM set-up

minimize
$$F_1(x) + F_2(z)$$

subject to : $x \in C_1$, $z \in C_2$
 $Ax = z$

- Can be obtained as a special case of the ADMM set-up
- To see this, let $z = (z_1, ..., z_m)$ and define $A = \begin{bmatrix} I \\ \vdots \\ I \end{bmatrix}$ (stack of identity matrices), hence $Ax = \begin{bmatrix} x \\ \vdots \\ x \end{bmatrix}$ and $Ax = z \Leftrightarrow \begin{bmatrix} x \\ \vdots \\ x \end{bmatrix} = \begin{bmatrix} z_1 \\ \vdots \\ z_m \end{bmatrix}$

ADMM algorithm

Effectively Augmented Lagrangian with one Gauss-Seidel pass

2
$$z(k+1) = \arg\min_{z \in C_2} F_2(z) - \lambda(k)^T z + \frac{c}{2} ||Ax(k+1) - z||^2$$

3
$$\lambda(k+1) = \lambda(k) + c(Ax(k+1) - z(k+1))$$

Theorem: Convergence of ADMM

Assume that the set of optimizers is non-empty, and either C_1 is bounded or A^TA is invertible. We then have that

- \bullet $\lambda(k)$ converges to an optimal dual variable.
- ② (x(k), z(k)) achieves the optimal value If A^TA invertible then it converges to an optimal primal pair

Hilary Term 2021-22

C20 Distributed Systems

2 12

January 28, 20

Decision coupled problems (cont'd)

Perform also the following assignments

$$F_1(\mathbf{x}) = 0, \quad C_1 = \mathbb{R}^n$$

$$F_2(z) = \sum_i f_i(z_i), \quad C_2 = X_1 \times \ldots \times X_m$$

- For each block constraint, i.e. $x = z_i$ assign the dual vector λ_i , and let $\lambda = (\lambda_1, \dots, \lambda_m)$
- The three ADMM steps become then

1
$$x(k+1) = \arg\min_{x \in \mathbb{R}^n} \lambda(k)^T Ax + \frac{c}{2} ||Ax - z(k)||^2$$

2
$$z(k+1) = \arg\min_{z_1 \in X_1, ..., z_m \in X_m} \sum_i f_i(z_i) - \lambda(k)^{\top} z + \frac{c}{2} ||Ax(k+1) - z||^2$$

3
$$\lambda(k+1) = \lambda(k) + c(Ax(k+1) - z(k+1))$$

14 / 28

Decision coupled problems (cont'd)

... or equivalently (compare with slide 5!)

- - Unconstrained quadratic optimization
 - Setting the gradient with respect to x equal to zero we obtain

$$\sum_{i} \lambda_{i}(k) + c \sum_{i} (x(k+1) - z_{i}(k)) = 0$$

$$\Rightarrow x(k+1) = \frac{1}{m} \sum_{i} z_{i}(k) - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

- 2 $z(k+1) = \arg\min_{z_1 \in X_1, \dots, z_m \in X_m} \sum_i \left(f_i(z_i) \lambda_i(k)^{\mathsf{T}} z_i + \frac{c}{2} \| x(k+1) x_i \|^2 \right)$
 - Since x(k+1) is fixed, fully separable across i. Minimizing the "sum" is equivalent to minimizing each individual component. Hence, for all i,

$$z_i(k+1) = \arg\min_{z_i \in X_i} f_i(z_i) - \lambda_i(k)^{\mathsf{T}} z_i + \frac{c}{2} ||x(k+1) - z_i||^2$$

3 $\lambda_i(k+1) = \lambda_i(k) + c(x(k+1) - z_i(k+1))$ (due to the structure of A)

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022 15 / 28

Constraint coupled problems

Original problem

minimize
$$\sum_{i} f_{i}(x_{i})$$

subject to : $x_{i} \in X_{i}, \ \forall i$

ADMM set-up

minimize
$$F_1(x) + F_2(z)$$

subject to : $x \in C_1$, $z \in C_2$

$$Ax = z$$

- To see this, let $x = (x_1, \dots, x_m)$, $z = (z_1, \dots, z_m)$ and A = identity matrix
- Separate complicated objective from complicated constraints

$$F_1(x) = \sum_i f_i(x_i), \quad C_1 = X_1 \times ... \times X_m$$

 $F_2(z) = 0, \quad C_2 = \{z \mid \sum_i z_i = 0\}$

Constraint coupled problems

Affine coupling:

minimize
$$\sum_{i} f_{i}(x_{i})$$

subject to : $x_{i} \in X_{i}, \forall i$
 $\sum_{i} x_{i} = 0$

- Affine coupling constraint : equality with zero for simplicity
- We could have general coupling constraints Ax = b; see Example 4.4. Chapter 3 in [Bertsekas & Tsitsiklis 1989]
- We can still treat as an ADMM example

4 D > 4 A > 4 B > 4 B > B = 40 0

Hilary Term 2021-22

C20 Distributed Systems

Constraint coupled problems

ADMM algorithm for constraint coupled problems

Primal update for x; in parallel for all agents

$$x_i(k+1) = \arg\min_{x_i \in X_i} f_i(x_i) + \lambda_i^{\top}(k)x_i + \frac{c}{2} ||x_i - z_i(k)||^2$$

Primal update for z information from central authority

$$z(k+1) = \arg\min_{\{z: \sum_{i} z_{i} = 0\}} - \sum_{i} \lambda_{i}^{\mathsf{T}}(k)z_{i} + \frac{c}{2} \sum_{i} ||x_{i}(k+1) - z_{i}||^{2}$$

3 Dual update $\lambda_i(k+1) = \lambda_i(k) + c(x_i(k+1) - z_i(k+1))$

Question 6, Example paper: Solve the z-minimization analytically

- Find unconstraint minimizer and project on $\sum_i z_i = 0$
- Notice that $\lambda_1(k) = \ldots = \lambda_m(k)$ for all $k \ge 1$

Part II.A: Distributed algorithms

Decision coupled problems

Distributed proximal minimization

General architecture

Step 1 : Local problem of agent i

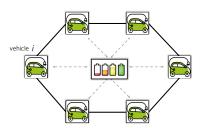

minimize
$$f_i(x_i) + g_i(x_i, z_i)$$

subject to $x_i \in X_i$ $\Rightarrow x_i^*(z_i)$

- x_i : "copy" of x maintained by agent i **NOT** an element of x
- X_i: local constraint set of agent i
- z_i : information vector constructed based on the info of agent's i neighbors
- Objective function
 - $f_i(x_i)$: local cost/utility of agent i
 - $g_i(x_i, z_i)$: Proxy term, penalizing disagreement with other agents

Recall electric vehicle charging control problem

Decision coupled problem

minimize
$$\sum_{i} f_i(x)$$
 subject to

$$E_{\infty} = \{(j, i) : (j, i) \in E_k \text{ for infinitely many } k\}.$$

 (V, E_{∞}) is strongly connected and (kind of) periodic, i.e., for any two nodes there exists a path of directed edges that connects.

- Any pair of agents communicates infinitely often,
- Intercommunication time is bounded

Hilary Term 2021-22

Algorithm analysis: Assumptions

3 Network connectivity – All information flows (eventually)

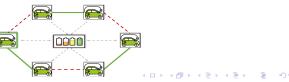

Connectivity

Let (V, E_k) be a directed graph, where V: nodes/agents, and $E_k = \{(j, i): a_i^j(k) > 0\}: \text{ edges Let}$

$$E_{\infty} = \{(j,i): (j,i) \in E_k \text{ for infinitely many } k\}.$$

 (V, E_{∞}) is strongly connected and (kind of) periodic, i.e., for any two nodes there exists a path of directed edges that connects.

- Any pair of agents communicates infinitely often,
- Intercommunication time is bounded

Convergence & optimality

C20 Distributed Systems

methods, i.e. instead of exchanging their tentative decisions, agents

Theorem: Convergence of distributed proximal minimization

Under the structural + network assumptions, the proposed proximal

algorithm converges to some minimizer x^* of the centralized problem, i.e.,

 $\lim_{k \to \infty} ||x_i(k) - x^*|| = 0$, for all i

• Rate no faster than c(k) – "slow enough" to trade among the two

objective terms, namely, agreement/consensus and optimality

• There are ways to speed things up : Average gradient tracking

4 D > 4 A > 4 B > 4 B > B = 40 0

Example (cont'd)

Two-agent problem equivalent reformulation

Asymptotic agreement and optimality

exchange their tentative gradients.

Let $\alpha > 0$ and $1 < M < \infty$, $s_1 = 1$, $s_2 = -1$, and consider

$$\min_{x \in \mathbb{R}} \qquad \sum_{i=1,2} \alpha (x + s_i)^2$$

subject to
$$x \in [-M, M]$$

- Agents' objective functions : $f_i(x) = \alpha(x + s_i)^2$, for i = 1, 2
- Objective function becomes : $2\alpha x^2 + 2\alpha$. Since $\alpha > 0$ its minimum is achieved at $x^* = 0$

Example

Two-agent problem

Let $\alpha > 0$ and $1 < M < \infty$, and consider the problem :

minimize_{$$x \in \mathbb{R}$$} $\alpha(x+1)^2 + \alpha(x-1)^2$
subject to $x \in [-M, M]$

- What is the optimal solution?
- 2 Compute it by means of the distributed proximal minimization algorithm using
 - Time-invariant mixing weights $a_i^i(k) = \frac{1}{2}$ for all iterations k

C20 Distributed Systems

- Take $c(k) = \frac{1}{k+1}$

Hilary Term 2021-22

- Initialize with $x_1(0) = -1$ and $x_2(0) = 1$
- Treat this as a two-agent decision coupled problem

January 28, 2022

Example (cont'd)

Main distributed proximal minimization updates

• Information mixing for i = 1, 2 (under our choice for mixing weights):

$$z_i(k) = \frac{x_1(k) + x_2(k)}{2}$$

2 Local computation for i = 1, 2:

$$x_i(k+1) = \arg\min_{x_i \in [-M,M]} \alpha(x_i + s_i)^2 + \frac{1}{2c(k)} ||x_i - z_i(k)||^2$$

- Information mixing is the same for all agents : $z_1(k) = z_2(k)$
- Local computation : Constrained quadratic problem ⇒ Find unconstrained minimizer and project it on [-M, M]
- Unconstrained minimizer :

$$\frac{z_i(k) - s_i 2\alpha c(k)}{2\alpha c(k) + 1}$$

Hilary Term 2021-22

Example (cont'd)

We will show by means of induction that $z_1(k) = z_2(k) = 0$

• Step 1: For k = 0, and since $x_1(0) = -1$ and $x_2(0) = 1$, we have that

$$z_i(0) = \frac{x_1(0) + x_2(0)}{2} = 0$$
, for $i = 1, 2$

- 2 Step 2: Induction hypothesis $z_1(k) = z_2(k) = 0$
- 3 Step 3: Show that $z_i(k+1) = 0$

$$\begin{aligned} x_i(k+1) &= \begin{cases} \min\left(\frac{-s_i 2\alpha c(k)}{2\alpha c(k)+1}, M\right), & \text{if } \frac{-s_i 2\alpha c(k)}{2\alpha c(k)+1} \geq 0 \\ \max\left(\frac{-s_i 2\alpha c(k)}{2\alpha c(k)+1}, -M\right), & \text{otherwise,} \end{cases} \\ &= -s_i \frac{2\alpha c(k)}{2\alpha c(k)+1}, \end{aligned}$$

where the first equality is due to the induction hypothesis, and the second is due to the fact that $\left|\frac{-s_i 2\alpha c(k)}{2\alpha c(k)+1}\right| < 1$ and M > 1, so the argument is never "clipped" to $\pm M$

Example (cont'd)

Main distributed proximal minimization updates

• Information mixing for i = 1, 2 (under our choice for mixing weights):

$$z_i(k) = \frac{x_1(k) + x_2(k)}{2}$$

2 Local computation for i = 1, 2:

$$\begin{aligned} x_i(k+1) &= \Pi_{[-M,M]} \left[\frac{z_i(k) - s_i 2\alpha c(k)}{2\alpha c(k) + 1} \right] \\ &= \begin{cases} \min\left(\frac{z_i(k) - s_i 2\alpha c(k)}{2\alpha c(k) + 1}, M\right), & \text{if } \frac{z_i(k) - s_i 2\alpha c(k)}{2\alpha c(k) + 1} \ge 0 \\ \max\left(\frac{z_i(k) - s_i 2\alpha c(k)}{2\alpha c(k) + 1}, -M\right), & \text{otherwise,} \end{cases} \end{aligned}$$

• What happens to $z_i(k)$ under our initialization choice?

4 □ ト 4 □ ト 4 亘 ト 4 亘 ・ 夕 Q ○

Hilary Term 2021-22

C20 Distributed Systems

Example (cont'd)

We will show by means of induction that $z_1(k) = z_2(k) = 0$

Step 1: For k = 0, and since $x_1(0) = -1$ and $x_2(0) = 1$, we have that

$$z_i(0) = \frac{x_1(0) + x_2(0)}{2} = 0$$
, for $i = 1, 2$

- 2 Step 2: Induction hypothesis $z_1(k) = z_2(k) = 0$
- 3 Step 3 : Show that $z_i(k+1) = 0$

$$x_{i}(k+1) = \begin{cases} \min\left(\frac{-s_{i}2\alpha c(k)}{2\alpha c(k)+1}, M\right), & \text{if } \frac{-s_{i}2\alpha c(k)}{2\alpha c(k)+1} \ge 0\\ \max\left(\frac{-s_{i}2\alpha c(k)}{2\alpha c(k)+1}, -M\right), & \text{otherwise,} \end{cases}$$
$$= -s_{i}\frac{2\alpha c(k)}{2\alpha c(k)+1}$$

• Since $s_1 + s_2 = 0$ we then have that

$$z_i(k+1) = \frac{x_1(k+1) + x_2(k+1)}{2} = -\frac{\alpha c(k)}{2\alpha c(k) + 1}(s_1 + s_2) = 0$$

Hilary Term 2021-22

C20 Distributed Systems

Example (cont'd)

Since $z_i(k) = 0$ for all k, the x-update steps become

x-update steps for i = 1, 2,

$$x_i(k+1) = -s_i \frac{2\alpha c(k)}{2\alpha c(k) + 1}$$
$$= -s_i \frac{2\alpha}{2\alpha + k + 1}$$

• As iterations increase, i.e. $k \to \infty$ we obtain that

$$\lim_{k\to\infty} x_i(k+1) = 0 = x^*$$

• In other words, the distributed proximal minimization algorithm converges to the minimum of the decision coupled problem

Hilary Term 2021-22

C20 Distributed Systems

4□ > 4回 > 4 重 > 4 重 > 重 の Q ○

January 28, 2022

Relationship with distributed proximal minimization

• Proximal algorithms can be equivalently written as a gradient step

$$x_{i}(k+1) = \arg\min_{x_{i} \in X_{i}} f_{i}(x_{i}) + \frac{1}{2c(k)} ||x_{i} - z_{i}(k)||^{2}$$

$$\Leftrightarrow x_{i}(k+1) = \prod_{x_{i}} \left[z_{i}(k) - c(k) \nabla f_{i}(x_{i}(k+1)) \right]$$

- Notice that this is no a recursion but an identity satisfied by $x_i(k+1)$ as this appears on both sides of the last equality
- What happens if we replace in the right-hand side the most updated information available to agent i at iteration k, i.e. $z_i(k)$?

C20 Distributed Systems

$$x_i(k+1) = \prod_{X_i} \left[z_i(k) - c(k) \nabla f_i(z_i(k)) \right]$$

• ... we obtain the distributed projected gradient algorithm!

Distributed projected gradient algorithm

Main update steps:

Hilary Term 2021-22

Averaging step in parallel for all agents

$$z_i(k) = \sum_i a_j^i(k) x_j(k)$$

2 Primal update for x_i in parallel for all agents (projection step)

$$x_i(k+1) = \prod_{X_i} \left[z_i(k) - c(k) \nabla f_i(z_i(k)) \right]$$

- The proxy term c(k) plays the role of the (diminishing) step-size along the gradient direction
- Convergence to the optimum under the same assumptions with distributed proximal minimization algorithm

C20 Distributed Systems

Distributed projected gradient algorithm

Main update steps:

Averaging step in parallel for all agents

$$z_i(k) = \sum_j a_j^i(k) x_j(k)$$

2 Primal update for x_i in parallel for all agents (projection step)

$$x_i(k+1) = \prod_{X_i} \left[z_i(k) - c(k) \nabla f_i(z_i(k)) \right]$$

- Looks similar with the distributed proximal minimization
- $\nabla f_i(z_i(k))$ denotes the gradient of f_i evaluated at $z_i(k)$
- The x-update is no longer "best response" but is replaced by the gradient step

$$z_i(k) - c(k) \nabla f_i(z_i(k))$$

projected on the set X_i Hilary Term 2021-22

Hilary Term 2021-22

4 D > 4 B > 4 B > 4 B > 9 Q C

Distributed projected gradient algorithm

Summary

Distributed algorithms for decision coupled problems

- Distributed proximal minimization
 - Step-size (proxy term) is now iteration varying
 - Convergence under assumptions on step-size, mixing weights and network connectivity
- Distributed projected gradient

Hilary Term 2021-22

- Rather than "best response" performs projected gradient step
- ► Same convergence assumptions with proximal minimization

| C20 Distributed Systems | January 28, 2022 | 19/21

The Gauss-Seidel algorithm

2 Agent *i* updates

 $x_i(k+1)$

differentiable

• Xi's are all convex

Main update steps (sequential algorithm):

C20 Distributed Systems

• F is strongly convex with respect to each individual argument, and

• Collect $x(k) = (x_1(k+1), \dots, x_{i-1}(k+1), x_i(k), \dots, x_m(k))$

 $= \arg\min_{\mathbf{x} \in X_i} F\left(x_1(\mathbf{k} + \mathbf{1}), \dots, x_{i-1}(\mathbf{k} + \mathbf{1}), x_i, x_{i+1}(\mathbf{k}), \dots, x_m(\mathbf{k})\right)$

4□ > 4□ > 4 = > 4 = > = 90

The Alternating Direction Method of Multipliers (ADMM)

Main update steps:

Primal update for z information from central authority

$$z(k+1) = \frac{1}{m} \sum_{i} x_{i}(k) - \frac{1}{mc} \sum_{i} \lambda_{i}(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i(k+1) = \arg\min_{x_i \in X_i} f_i(x_i) - \lambda_i(k)^{\mathsf{T}} x_i + \frac{c}{2} ||z(k+1) - x_i||^2$$

3 Dual update in parallel for all agents

$$\lambda_i(k+1) = \lambda_i(k) + c(z(k+1) - x_i(k+1))$$

• Augmented Lagrangian with one Gauss-Seidel pass of the inner loop

Decision coupled problems

Decision coupled problems

minimize
$$\sum_{i} f_i(x)$$

subject to

$$x \in X_i, \forall i = 1, \dots m$$

ADMM algorithm (more general form)

Applicable to problems with two groups of variables:

minimize
$$F_1(x) + F_2(z)$$

subject to : $x \in C_1$, $z \in C_2$
 $Ax = z$

Main update steps:

2
$$z(k+1) = \arg\min_{z \in C_2} F_2(z) - \lambda(k)^T z + \frac{c}{2} ||Ax(k+1) - z||^2$$

3
$$\lambda(k+1) = \lambda(k) + c(Ax(k+1) - z(k+1))$$

Convergence:

• All functions and sets are convex, and $A^{T}A$ is invertible

Hilary Term 2021-22

C20 Distributed Systems

January 28, 2022

Distributed proximal minimization

Main update steps:

Averaging step in parallel for all agents

$$z_i(k) = \sum_j a_j^i(k) x_j(k)$$

2 Primal update for x_i in parallel for all agents

$$x_i(k+1) = \arg\min_{x_i \in X_i} f_i(x_i) + \frac{1}{2c(k)} ||x_i - z_i(k)||^2$$

Convergence:

- Convexity of all functions and sets + Network connectivity (slide 7)
- Mixing weights sum up to one, forming a doubly stochastic matrix
- Step-size choice : $c(k) = \frac{\alpha}{k+1}$, $\alpha > 0$

Decision coupled problems

Part II.A: Distributed algorithms

Decision coupled problems

minimize
$$\sum_{i} f_i(x)$$
